Walnutdale Dairy CAFO

Home H-5,6,7 Manure app review

Mr. Lettinga,

On April 12th, we began a review on the manure application records for the H567 field to determine the nitrogen content from manure applications. The nitrogen values on the DEQ annual report were determined by putting the application rates into the Purdue Manure Management Program (MMP) that is used to track nutrient values and applications. Below I will outline a review of manure applications on this field and some of the historical data we have showing that the manure applied for the 2012 cropping season was not providing the 440lbs N/acre that was generated by the MMP program.

At the current time, Walnutdale dairy does not have a sample on the solid manure that is applied from the bottom of the lagoon storage when it is cleaned out. When this storage structure is scrapped out, a sample will be submitted to determine the nutrient value. It is our belief that the current values being used (estimated at TKN – 25#/ton, AN-15#/T, ON-10#/ton) are over estimating the nitrogen content of that manure.

Estimated Nitrogen Value from Manure:

Ammonia Nitrogen = 15#/ton x .70 (nitrogen retention factor based on 24hour incorporation) results in 10.5#N/ton of manure applied

Organic Nitrogen = 10#/ton x .3 (mineralization factor for dairy manure) = 3.3#/ton of manure

Total Nitrogen = AN+ON = 10.5 + 3.3 = 13.8 #/Ton of manure

2010 Manure applications towards 2011 crop production:

Manure applied 11/1 to 11/15 of 2010 on this field at a rate of 19 tons/acre

Manure applied @ 19T/acre x 13.8#N/ton = 262.2# of nitrogen projected to be available for 2011 cropping season

June 13 of 2011 a PreSidedress Nitrate test was taken from the H567 field (A&L Lab report submitted as well) that shows the available nitrate in the soil solution was at 15&16 parts per million (ppm). When these values are reviewed using the A&L Labs Presidress Soil Nitrate Testing charts (provided with this information) it shows that the nitrogen in the soil solution is insufficient for crop production (175bu/acre corn) and is calling for an additional 75-150#/acre of nitrogen to meet those needs.

This review shows that the projected available nitrogen number of 262.2#/acre is not accurate. The nitrogen available for crop production is far less than the estimated value.

2011 Manure Applications towards 2012 crop production:

Manure from the bottom of the storage was applied again on 12/10-18/2011 on the H567 field. Based on the number of loads, the estimated rate is 31T/acre (approx. 9,000 gallons using a 50#/cubic foot density of manure).

Manure applied @ 31T/acre x 13.8#N/ton = 427.8#N/acre projected available

On May 21 of 2012 an application of 6,400 gallons/acre of water from the catch basin was irrigated over the top of the corn crop.

Catch basin nutrient availability: AN - .9#/1,000 gallons, ON - .7#/1,000 gallons

6400 gallon/acre application rate results in the following available nitrogen:

Ammonia Nitrogen – all lost due to volatilization

Organic Nitrogen - .7#/1000 gal x .3 (mineralization factor) = .21#N/1000 gallons applied

Total Nitrogen from irrigation application is estimated at 1.34#N/acre

Based on the review from 2011 pit solid applications, the estimated available nitrogen is a significant overestimation of the nutrient value of the pit solid manure. A PSNT sample was not taken during the 2012 growing season to determine the nitrates in the soil solution during the growing season.

2013 Plans:

Walnutdale Dairy will collect a manure sample of the pit solids when the storage structure is being scraped out. This sample will be submitted to A&L Labs to establish an accurate nutrient value. Presidedress nitrogen tests will be taken to determine the nitrogen available in the soil structure during the 2013 growing season. Nitrogen will be applied (or not applied) to the H567 field based on the PSNT test results and targeted crop production.

If there are any questions on this information, or on the calculations used to determine these values, please feel free to contact me.

Respectfully,

A handwritten signature in black ink, appearing to read 'Jason Stegink', with a long horizontal flourish extending to the right.

Presidedress Soil Nitrate Testing (PSNT) for Corn

FACT SHEET

WHY TEST?

While nitrogen is a critical nutrient for corn production, it is also a major contributor to the high cost of production. In addition, since nitrogen is mobile in the soil, it can move into surface or ground waters, which is an environmental and water quality concern. Nitrogen rates should be fine tuned to maximize economic returns and limit environmental impacts associated with inefficient uses of nitrogen fertilizer.

The behavior of nitrogen in the soil is complex. Nitrogen is plant available as either ammonium (NH_4) or nitrate (NO_3). Ammonium has a positive charge and can attach to the surface of soil particles. This prevents much of the ammonium from being removed from the soil profile by leaching. However, a number of processes in the soil naturally convert ammonium into nitrate. Nitrogen in the nitrate form has a negative charge and does not attach to soil particles. Therefore, nitrate can be lost as water moves through the soil profile. In addition to losses by leaching, nitrate can also be lost in situations where oxygen is limiting, such as in saturated soils. In this situation, nitrates are converted into gases that are not plant available and can be lost to the atmosphere.

Since nitrogen is generally not retained by the soil in the same manner as other plant nutrients, excess nitrogen applied to a crop is generally not available to subsequent crops. However, in situations of limited rainfall, nitrate may be carried over from the previous growing season and reduce the need for nitrogen fertilizer.

Organic materials in the soil can also be a significant source of nitrogen for plant growth. Nitrogen is continually being released from organic sources such as applied manure, crop residues, and soil organic matter as these materials decompose (mineralize). Since this process is highly dependant on a number of factors, it is not possible to predict the amount of nitrogen that will be released by mineralization.

The PSNT is most beneficial in situations where manure has been applied to a field, or where a recent legume forage crop, such as alfalfa, has been grown. These practices generally provide higher levels of potentially available nitrogen to the

growing crop. Since the contribution of available nitrogen from these sources is variable due to several factors, the PSNT can be a useful tool for assessing the actual nitrogen contribution from these sources.

SAMPLING

Time: Take samples in the spring when the corn is 6 -12 inches tall or at least a week before a planned sidedress application to allow adequate time for laboratory analysis and interpretation of the data.

Depth: Samples should be collected to a depth of 12 inches. All of the interpretative guidelines presented in this fact sheet are based on 12 inch sample depth. Take at least 10 to 15 cores per sample unit.

Place: Since the PSNT measures the nitrate released by mineralization of organic materials, factors that affect mineralization should be considered when determining the sampled area. Factors such as soil type and slope, as well as differences in management, including intensity of artificial drainage, rates of manure application, and cropping history, should be considered when determining sampling areas. Avoid starter bands or other unusual areas. In addition, **if high rates of nitrogen fertilizers have been applied pre-plant or at planting, PSNT values may not provide an accurate assessment of the nitrogen status of the soil.** A general guideline is that one sample should represent no more than 15 – 20 acres.

Handling: The soil from all cores should be crushed and thoroughly mixed before a 1-2 cup subsample is removed for analysis. Samples should be shipped immediately after collection so that they may be analyzed within 2 days. Samples may be refrigerated, frozen, or dried for preservation if they cannot be shipped immediately. Do not exceed a temperature of 250°F in drying.

Shipping: Ship via UPS or courier for best results. Moist samples sent Monday - Wednesday should arrive without weekend delays, which could affect results.

INTERPRETATION OF RESULTS

Not all states have recommended nitrate sampling programs. Interpretative guidelines for several states are outlined below:

	16-25	0	30
	>25	0	0

* Pm-1714, *Nitrogen Fertilizer Recommendations for Corn in Iowa*, Iowa State University

¹ A critical concentration of 25 ppm NO₃-N is appropriate in absence of additional information. Reduce the critical concentration by 3-5 ppm if rainfall is more than 20% above normal amount between April 1 and time of soil sampling.

² A field should be considered manured if animal manures were applied with a reasonable degree of uniformity since harvest of the previous crop or in 2 of the past 4 years.

³ Rainfall should be considered excess if rainfall in May exceeded 5 inches.

⁴ Addition of 30 lb. N/acre may have no detectable effects on profits, but producers could reasonably elect to apply this rate.

0-10	0	0

* UWEX publication A2809, *Nutrient Application Guidelines for Field, Vegetable and Fruit Crops in Wisconsin*

** No additional nitrogen fertilizer is recommended.

¹ Refer to UWEX publication A2809 to determine soil yield potential. PSNT is not recommended on sandy soils (loamy sands and sands).

² Refer to UWEX publication A2809 for a discussion of other factors that affect N guidelines.
